

Questions week 2 javascript

Patrick Jonk

- 0 Javascript performs automatic type conversion of variables if they are compared using the == operator and are not the same type. Using === prevents this. If two variables are not of the same type, they will never be equal.
- 1 If a variable is declared within a function it only exists within that function. Closures are special type of function, in which the function has access to the parent scope.
- 2 Higher order functions are functions that operate on other functions.
- 3 Query selectors are used to find DOM elements. Example: return `document.querySelectorAll(selector).length;`
